

House Price Prediction - Project Summary

Insights and Summary

From the analysis, I found that area has the biggest impact on house prices, followed by bathrooms, air conditioning, parking, and the number of stories. I trained and compared two models, Linear Regression and Random Forest Regressor. Linear Regression gave better results with an R^2 score of 0.653, which means it was able to explain around 65% of the changes in house prices. One thing that surprised me was how much facilities like air conditioning and parking affected the price of a house. Based on these results, I think real estate businesses should pay special attention to property size and important amenities while deciding house prices.

Conclusion

In this project, I built a house price prediction model using machine learning techniques and analyzed the factors that affect house prices. After comparing Linear Regression and Random Forest Regressor, Linear Regression performed better on this dataset. The analysis showed that area, bathrooms, and amenities such as air conditioning and parking play an important role in determining house prices. This project helped me understand the complete machine learning workflow, including data cleaning, visualization, model training, evaluation, and interpretation of results.
